1.2.1 Generating Data and Models

The data generating model used was from Appendix 3 of Bowden et al (ref); the relevant section describing their model is reproduced below:

"...

$$U_i = \sum_{j=1}^{J} \phi_j G_{ij} + \epsilon_i^U \tag{1}$$

$$X_i = \sum_{j=1}^{J} \gamma_j G_{ij} + U_i + \epsilon_i^X \tag{2}$$

$$Y_i = \sum_{j=1}^{J} \alpha_j G_{ij} + \beta X_i + U_i + \epsilon_i^Y$$
(3)

for participants indexed by i = 1, ..., N, and genetic instruments indexed by j = 1, ..., J.

The error terms ϵ_i^U , ϵ_i^X and ϵ_i^Y were each drawn independently from standard normal distributions. The genetic effects on the xposure j are drawn from a uniform distribution between 0.03 and 0.1. Pleiotropic effects α_j and ϕ_j were set to zero if the genetic instrument was a alid instrumental variable. Otherwise (with probability 0.1, 0.2, or 0.3):

- 1. In Scenario 1 (balanced pleiotropy, InSIDE satisfied), the α_j parameter was drawn from a uniform distribution between -0.2 and 0.2.
- 2. In Scenario 2 (directional pleiotropy, InSIDE satisfied), the α_j parameter was drawn from a uniform distribution between 0 and 0.2.
- 3. In Scenario 3 (directional pleiotropy, InSIDE not satisfied), the ϕ_j parameter was drawn from a uniform distribution between -0.2 and 0.2.

The causal effect of the exposure on the outcome was either $\beta X=0$ (null causal effect) or $\beta X=0.1$ (positive causal effect). A total of 10 000 simulated datasets were generated for sample sizes of N=10 000 and

20 [sic] participants. Only the summary data, that is genetic associations with the exposure and with the outcome and their standard errors as estimated by univariate regression on the genetic instruments in turn, were used by the analysis methods. In the two-sample setting, data were generated on 2N participants, and genetic associations with the exposure were estimated in the first N participants, and genetic associations with the outcome in the second N participants."?

To reproduce this model, code was written in R to generate the relevant participant level data. First, a function (simulate_MR_data) was written which included arameters specified by Bowden et al, and also to allow testing of data simulation:

```
# Define function to create data generating model
# Arguments/default values based on Bowden et al
simulate_MR_data <- function(n_participants = as.integer(),</pre>
                               n instruments = as.integer(),
                               n_datasets = as.integer(),
                               prop_invalid = 0.1,
                               causal_effect = TRUE,
                               balanced pleio = TRUE,
                               InSIDE_satisfied = TRUE,
                               rand error = TRUE,
                                                      # remove random errors, for testing
                               two_sample = TRUE,
                                                       # 1- or 2-sample MR toggle, for testing
                               beta_val = 0.1,
                                                       # size of causal effect
                               allele_freq_min = 0.01,# frequency of effect allele
                               allele_freq_max = 0.99,
                               gamma_min = 0.03,
                                                       # size of pleiotropic effects on exposure
                               gamma_max = 0.1,
                               alpha_min = -0.2,
                                                       # size of pleiotropic effects on outcome
                               alpha_max = 0.2,

A function (extract_models) was then written to create linear models from each dataset generated as per Bowden et al:

```
# Create plotting tibble with Mean/SD X + Y grouped by
# Dataset + instrument
extract_models <- function(sim){</pre>
   output_list <- list()</pre>
  # Create linear models per dataset to get coefficients
  # for gene:exposure association (coeff_G_X) and gene:outcome
  \# association (coeff_G_Y)
   for(dataset in 1:length(sim$X)){
     X <- sim$X[[dataset]]</pre>
     Y <- sim$Y[[dataset]]</pre>
     Instruments_X <- sim$G_X[[dataset]]</pre>
     Instruments_Y <- sim$G_Y[[dataset]]</pre>
     alpha <- sim$alpha[[dataset]]</pre>
     gamma <- sim$gamma[[dataset]]</pre>
     phi <- sim$phi[[dataset]]</pre>
     beta <- sim$beta[[dataset]]</pre>
     prop_invalid <- sim$prop_invalid[[dataset]]</pre>
    # Model for gene:exposure
     X_lm <- lm(X ~ 0 + Instruments_X)</pre>
     coeff_G_X_vect <- coef(summary(X_lm))[1:(ncol(Instruments_X)), 1]</pre>
     SE_coeff_G_X_vect <- coef(summary(X_lm))[1:(ncol(Instruments_X)), 2]</pre>
    # Model for gene:outcome
     Y lm \leftarrow lm(Y \sim 0 + Instruments Y)
     coeff_G_Y_vect <- coef(summary(Y_lm))[1:(ncol(Instruments_Y)), 1]</pre>
```

```
SE_coeff_G_Y_vect <- coef(summary(Y_lm))[1:(ncol(Instruments_Y)), 2]</pre>
    output_list[[dataset]] <- as_tibble(list(dataset = dataset,</pre>
                                                Instrument = c(1:ncol(Instruments_X)),
                                               coeff_G_X = coeff_G_X_vect,
                                               coeff_G_X_SE = SE_coeff_G_X_vect,

                                               prop_invalid = prop_invalid),
                                          .name_repair = "unique")
  }
  return(output_list)
}
```

These models generated estimates of the coefficient of gene:exposure association (coeff_G_X), coefficient of gene:outcome association (coeff_G_Y), and the elevant standard errors of these estimates. The values of parameters inputted were also returned to aid in further testing of data/model generation, i.e. actual ene:exposure associations (gamma), pleiotropic effects of invalid instruments (alpha), additional pleiotropic effects when InSIDE assumption not satisfied phi), causal effect of exposure on outcome (beta) and the proportion of invalid genetic instruments with pleiotropic effects on the outcome (prop_invalid).

```
test_extract_model <- extract_models(test_data_sim)
summary(test_extract_model[[1]])</pre>
```

```

1.2.2 Testing Generation of Data and Models

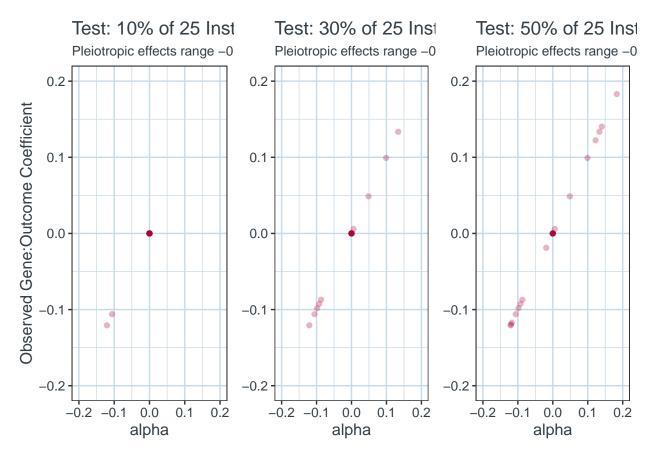

A series of test plots were used to verify that data were simulated as intended under the various conditions specified by input parameters. Test plots were not reated for the parameters n_participants, n_instruments or n_datasets, as the functioning of these parameters could be readily inferred from the structure of he datasets outputted, as above.

The prop_invalid parameter specifies the proportion of invalid genetic instruments simulated, i.e. the proportion of genetic instruments affecting the outcome via irect/pleiotropic effects, and thus not solely via the exposure of interest. If simulated correctly, increasing the value of $prop_invalid$ should increase the umber of instruments with pleiotropic effects, i.e. instruments with alpha = /= 0. With random error terms set to 0 and no causal effect present (i.e. $rand_error = ALSE$ and $causal_effect = FALSE$), the estimated gene:outcome coefficient estimated using any given instrument will equal the pleiotropic effects of that instrument i.e. $coeff_G_Y = alpha$), and therefore will only be non-zero for invalid instruments with non-zero pleiotropic effects on the outcome . Plotting $coeff_G_Y$ gainst alpha for simulated data with no causal effect or random error should therefore yield a graph where

- For valid instruments: gene:outcome coefficient = alpha = 0
- For invalid instruments: gene:outcome coefficient = alpha =/= 0, with values spread uniformly between alpha_min and alpha_max

```
# Check altering proportion of invalid instruments alters
# proportion of instruments displaying pleiotropic effects
# N.B. cluster around alpha = 0 represents valid instruments with
# no pleiotropic effects
# 10% of instruments invalid
set.seed(1701)

```

Similarly, with random error terms set to 0 and no causal effect present, gene:exposure coefficients estimated for each instrument should exactly match the actual alues simulated, i.e. $coeff_G_X = gamma$ for all instruments:

```
# Check observed gene: exposure coefficients for each instrument
# (coeff_GX) approximate true values (gamma) when a causal effect
# is present & a large number of participants are included
set.seed(1701)
sim_test_data_gamma_1 <- simulate_MR_data(n_participants = 100,</pre>
                                            n_{instruments} = 25,
                                            n_{datasets} = 1,
                                            prop invalid = 0.1,
                                            causal_effect = FALSE,
                                            rand_error = FALSE,
                                            balanced_pleio = TRUE,
                                            InSIDE_satisfied = TRUE)
